

Project Initialization and Planning Phase

Date	1 July 2026
Team ID	xxxxxxx
Project Name	Credit Card Approval Prediction
Maximum Marks	3 Marks

Define Problem Statements :

Banks and financial institutions process a large number of credit card applications every day, making manual evaluation increasingly difficult, time-consuming, and prone to human error. Traditional screening methods require analysts to review each applicant's financial and demographic information, which can lead to inconsistent decisions, delayed approvals, and increased operational costs. Additionally, identifying high-risk applicants while maintaining fair and accurate decision-making is a significant challenge.

The objective of this project is to develop an intelligent credit card approval prediction system using machine learning. By analyzing historical applicant data, the system predicts whether a new credit card application is likely to be approved or rejected based on factors such as income, employment status, family status, education, housing type, credit history, and financial behavior. Multiple classification algorithms are trained and evaluated to identify the most accurate model, which is then deployed through a Flask web application and IBM Watson Machine Learning for scalable, real-time predictions. The solution aims to improve decision accuracy, reduce processing time, assist financial institutions in risk assessment, and provide applicants with an instant eligibility prediction.
